## Low-Standby Power High Performance PWM Controller

The NCP1230 represents a major leap towards achieving low standby power in medium-to-high power Switched-Mode Power Supplies such as notebook adapters, off-line battery chargers and consumer electronics equipment. Housed in a compact 8-pin package (SOIC-8, SOIC-7, or PDIP-7), the NCP1230 contains all needed control functionality to build a rugged and efficient power supply. The NCP1230 is a current mode controller with internal ramp compensation. Among the unique features offered by the NCP1230 is an event management scheme that can disable the front-end PFC circuit during standby, thus reducing the no load power consumption. The NCP1230 itself goes into cycle skipping at light loads while limiting peak current (to 25% of nominal peak) so that no acoustic noise is generated. The NCP1230 has a high-voltage startup circuit that eliminates external components and reduces power consumption.

The NCP1230 also features an internal latching function that can be used for OVP protection. This latch is triggered by pulling the CS pin above 3.0 V and can only be reset by pulling V<sub>CC</sub> to ground. True overload protection, internal 2.5 ms soft-start, internal leading edge blanking, internal frequency dithering for low EMI are some of the other important features offered by the NCP1230.

### Features

- Current-Mode Operation with Internal Ramp Compensation
- Internal High-Voltage Startup Current Source for Loss-Less Startup
- Extremely Low No-Load Standby Power
- Skip-Cycle Capability at Low Peak Currents
- Direct Connection to PFC Controller for Improved No-Load Standby Power
- Internal 2.5 ms Soft-Start
- Internal Leading Edge Blanking
- Latched Primary Overcurrent and Overvoltage Protection
- Short-Circuit Protection Independent of Auxiliary Level
- Internal Frequency Jittering for Improved EMI Signature
- +500 mA/-800 mA Peak Current Drive Capability
- Available in Three Frequency Options: 65 kHz, 100 kHz, and 133 kHz
- Direct Optocoupler Connection
- SPICE Models Available for TRANSient and AC Analysis
- Pb-Free Packages are Available

### Typical Applications

- High Power AC-DC Adapters for Notebooks, etc.
- Offline Battery Chargers
- Set-Top Boxes Power Supplies, TV, Monitors, etc.

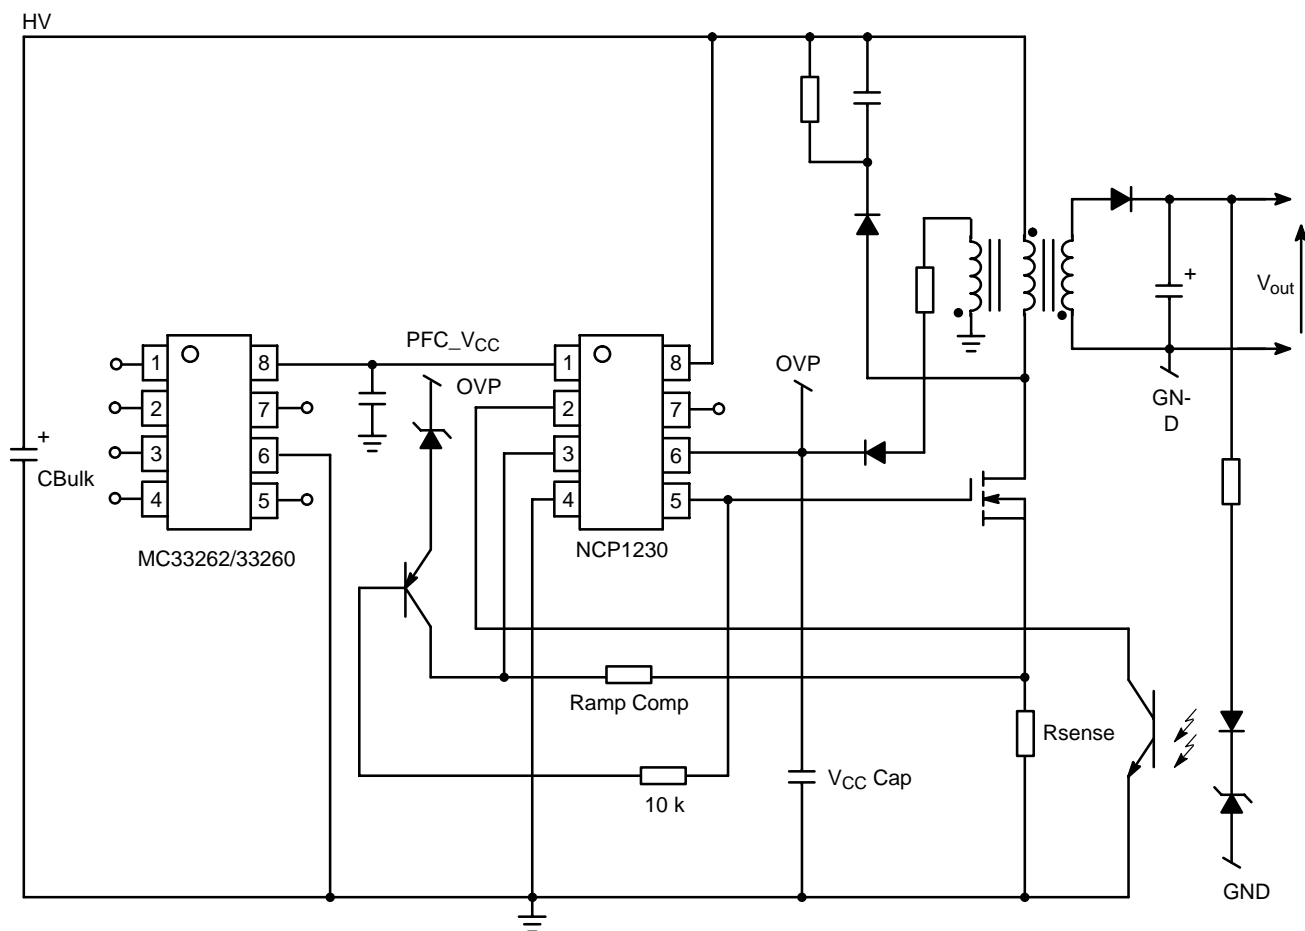

Figure 1. Typical Application Example

## PIN FUNCTION DESCRIPTION

Pin No.	Pin Name	Function	Pin Description
1	PFC V <sub>CC</sub>	This pin provides the bias voltage to the PFC controller.	This pin is a direct connection to the V <sub>CC</sub> pin (Pin 6) via a low impedance switch. In standby and during the startup sequence, the switch is open and the PFC V <sub>CC</sub> is shut down. As soon as the aux. winding is stabilized, Pin 1 connects to the V <sub>CC</sub> pin and provides bias to the PFC controller. It goes down in standby and fault conditions.
2	FB	Feedback Signal	An optocoupler collector pulls this pin low to regulate. When the current setpoint reaches 25% of the maximum peak, the controller skips cycles.
3	CS/OVP	Current Sense	This pin incorporates three different functions: the current sense function, an internal ramp compensation signal and a 3.0 V latch-off level which latches the output off until V <sub>CC</sub> is recycled.
4	GND	IC Ground	–
5	DRV	Driver Output	With a drive capability of +500 mA / –800 mA, the NCP1230 can drive large Qg MOSFETs.
6	V <sub>CC</sub>	V <sub>CC</sub> Input	The controller accepts voltages up to 18 V and features a UVLO turn-off threshold of 7.7 V typical.
7	NC	–	–
8	HV	High-Voltage	This pin connects to the bulk voltage and offers a lossless startup sequence. The charging current is high enough to support the bias needs of a PWM controller through Pin 1.

## MAXIMUM RATINGS (Notes 1 and 2)

Rating	Symbol	Value	Unit
Maximum Voltage on Pin 8 Maximum Current	$V_{DS}$ $I_{C2}$	–0.3 to 500 100	V mA
Power Supply Voltage, Pin 6 Current	$V_{CC}$ $I_{CC2}$	–0.3 to 18 100	V mA
Drive Output Voltage, Pin 5 Drive Current	$V_{DV}$ $I_o$	18 1.0	V A
Voltage Current Sense Pin, Pin 3 Current	$V_{CS}$ $I_{CS}$	10 100	V mA
Voltage Feedback, Pin 2 Current	$V_{fb}$ $I_{fb}$	10 100	V mA
Voltage, Pin 1 Maximum Continuous Current Flowing from Pin 1	$V_{PFC}$ $I_{PFC}$	18 35	V mA
Thermal Resistance, Junction–to–Air, PDIP Version	$R_{\theta JA}$	100	°C/W
Thermal Resistance, Junction–to–Air, SOIC Version	$R_{\theta JA}$	178	°C/W
Maximum Power Dissipation @ $T_A = 25^{\circ}\text{C}$	PDIP SOIC $P_{max}$	1.25 0.702	W
Maximum Junction Temperature	$T_J$	150	°C
Storage Temperature Range	$T_{stg}$	–60 to +150	°C

Maximum ratings are those values beyond which device damage can occur. Maximum ratings applied to the device are individual stress limit values (not normal operating conditions) and are not valid simultaneously. If these limits are exceeded, device functional operation is not implied, damage may occur and reliability may be affected.

1. This device series contains ESD protection and exceeds the following tests:

Pin 1–6: Human Body Model 2000 V per Mil–Std–883, Method 3015.

Machine Model Method 200 V

Pin 8 is the HV startup of the device and is rated to the maximum rating of the part, or 500 V.

2. This device contains latchup protection and exceeds 100 mA per JEDEC Standard JESD78.

## OPERATING DESCRIPTION

### Introduction

The NCP1230 is a current mode controller which provides a high level of integration by providing all the required control logic, protection, and a PWM Drive Output into a single chip which is ideal for low cost, medium to high power off-line application, such as notebook adapters, battery chargers, set-boxes, TV, and computer monitors.

The NCP1230 can be connected directly to a high voltage source providing lossless startup, and eliminating external startup circuitry. In addition, the NCP1230 has a PFC\_V<sub>CC</sub> output pin which provides the bias supply power for a Power Factor Correction controller, or other logic. The NCP1230 has an event management scheme which disables the PFC\_V<sub>CC</sub> output during standby, and overload conditions.

### PFC\_V<sub>CC</sub>

As shown on the internal NCP1230 diagram, an internal low impedance switch SW1 routes Pin 6 (V<sub>CC</sub>) to Pin 1 when the power supply is operating under nominal load conditions. The PFC\_V<sub>CC</sub> signal is capable of delivering up to 35 mA of continuous current for a PFC Controller, or other logic.

Connecting the NCP1230 PFC\_V<sub>CC</sub> output to a PFC Controller chip is very straight forward, refer to the “Typical Application Example” all that is generally required is a small decoupling capacitor (0.1 µF).

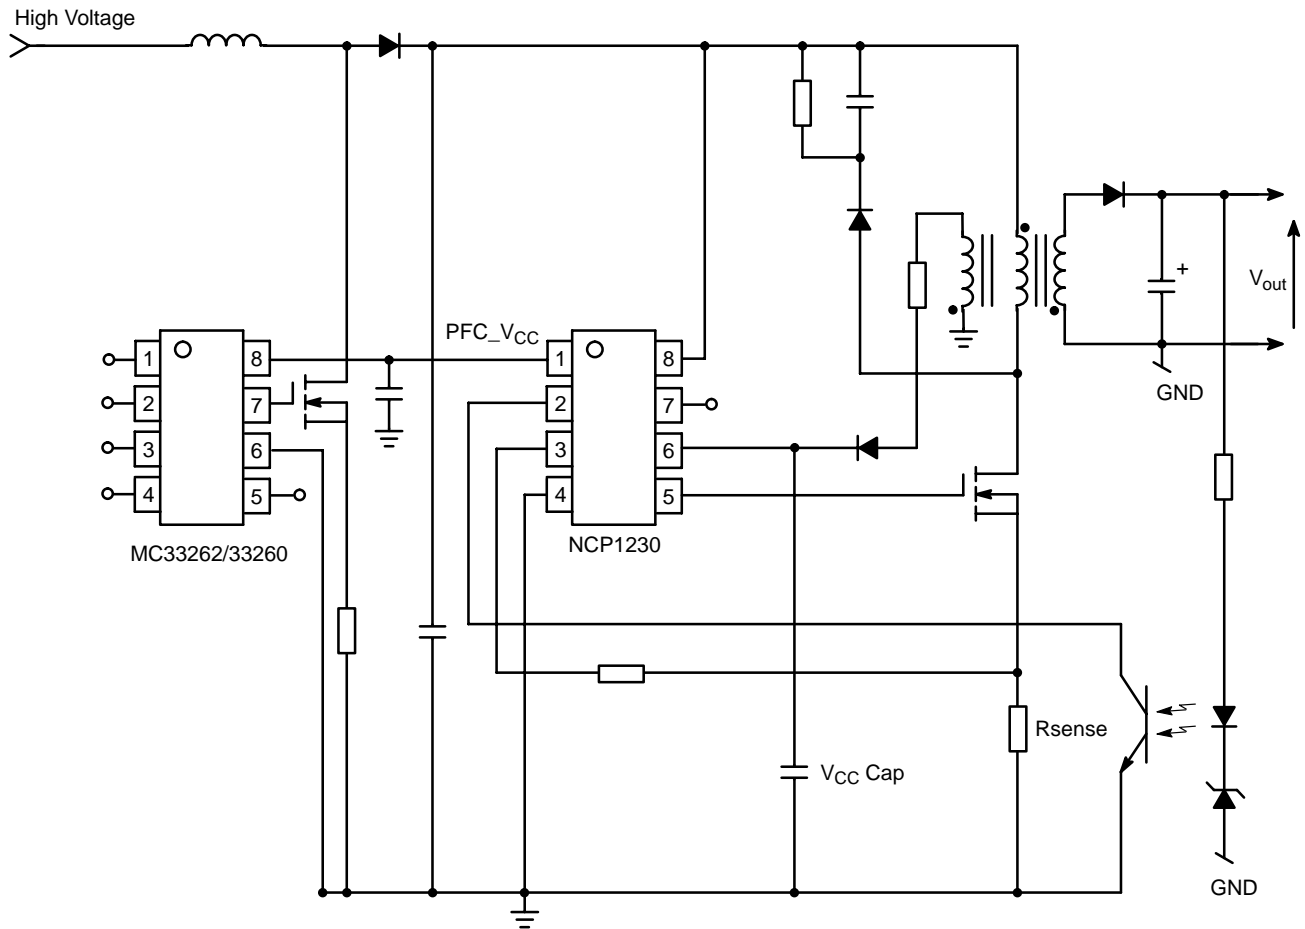

Figure 29. Typical Application Example

NCP1230 confirms that the low output power condition is present, and the internal SW1 opens, and the PFC\_Vcc signal output is shuts down. While the NCP1230 is in the skip mode the FB pin will move around the 750 mV threshold level, with approximately 100 mVp-p of hysteresis on the skip comparator, at a period which depends upon the (light) loading of the power supply and its various time constants. Since this ripple amplitude superimposed over the FB pin is lower than the second threshold (1.25 volt), the PFC\_Vcc comparator output stays high (PFC\_Vcc output Pin 1 is low).

In Phase four, the output power demands have increases and the feedback voltage rises above the 1.25 volts threshold, the NCP1230 exits the skip mode, and returns to normal operation.

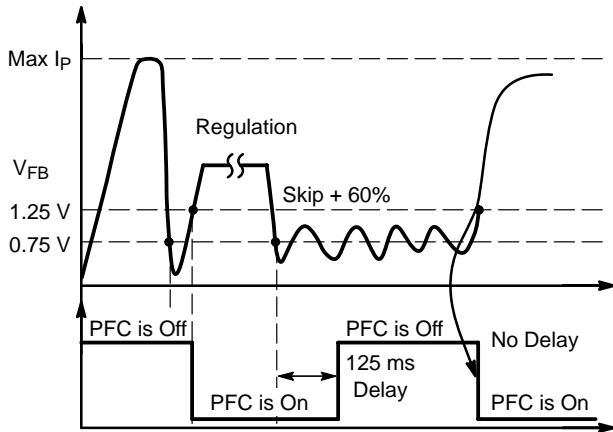

Figure 32.

#### Leaving Standby (Skip Mode)

When the feedback voltage rises above the 1.25 volts reference (leaving standby) the skip cycle activity stops and SW1 immediately closes and restarts the PFC, there is no delay in turning on SW1 under these conditions, refer to Figure 32.

#### Current Sense

The NCP1230 is a peak current mode controller, where the current sense input is internally clamped to 1.0 V, so the sense resistor is determined by  $R_{sense} = 1.0 \text{ V} / I_{pk}$  maximum.

There is a 18k resistor connected to the CS pin, the other end of the 18k resistor is connect to the output of the internal oscillator for ramp compensation (refer to Figure 33).

#### Ramp Compensation

In Switch Mode Power Supplies operating in Continuous Conduction Mode (CCM) with a duty-cycle greater than 50%, oscillation will take place at half the switching frequency. To eliminate this condition, Ramp Compensation can be added to the current sense signal to cure sub harmonic oscillations. To lower the current loop gain one typically injects between 50 and 100% of the inductor down slope.

The NCP1230 provides an internal 2.3 Vpp ramp which is summed internally through a 18 kΩ resistor to the current sense pin. To implement ramp compensation a resistor needs to be connected from the current sense resistor, to the current sense pin 3.

Example:

If we assume we are using the 65 kHz version of the NCP1230, at 65 kHz the dv/dt of the ramp is 130 mV/μs. Assuming we are designing a FLYBACK converter which has a primary inductance,  $L_p$ , of 350 μH, and the SMPS has a +12 V output with a  $N_p:N_s$  ratio of 1:0.1. The OFF time primary current slope is given by:

$$\frac{(V_{out} + V_f) \cdot \frac{N_s}{N_p}}{L_p} = 371 \text{ mA}/\mu\text{s} \text{ or } 37 \text{ mV}/\mu\text{s}$$

when imposed on a current sense resistor ( $R_{sense}$ ) of 0.1 Ω. If we select 75% of the inductor current downslope as our required amount of ramp compensation, then we shall inject 27 mV/μs.

With our internal compensation being of 130 mV, the divider ratio (*divratio*) between  $R_{comp}$  and the 18 kΩ is 0.207. Therefore:

$$R_{comp} = \frac{18k \cdot \text{divratio}}{(1 - \text{divratio})} = 4.69 \text{ k}\Omega$$

Figure 33.

### Leading Edge Blanking

In Switch Mode Power Supplies (SMPS) there can be a large current spike at the beginning of the current ramp due to the Power Switch gate to source capacitance, transformer interwinding capacitance, and output rectifier recovery time. To prevent prematurely turning off the PWM drive output, a Leading Edges Blanking (LEB) (Figure 34) circuit is placed in series with the current sense input, and PWM comparator. The LEB circuit masks the first 250 ns of the current sense signal.

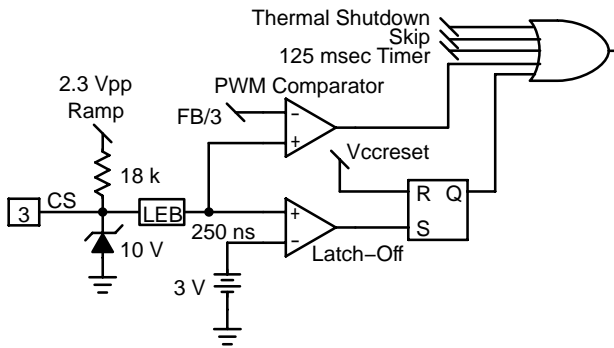

Figure 34.

### Short-Circuit Condition

The NCP1230 is different from other controllers which use an auxiliary windings to detect events on the isolated secondary output. There maybe some conditions (for example when the leakage inductance is high) where it can be extremely difficult to implement short-circuit and overload protection. This occurs because when the power switch opens, the leakage inductance superimposes a large spike on the switch drain voltage. This spike is seen on the

isolated secondary output and on the auxiliary winding. Because the auxiliary winding and diode form a peak rectifier, the auxiliary Vcc capacitor voltage can be charged up to the peak value rather than the true plateau which is proportional to the output level.

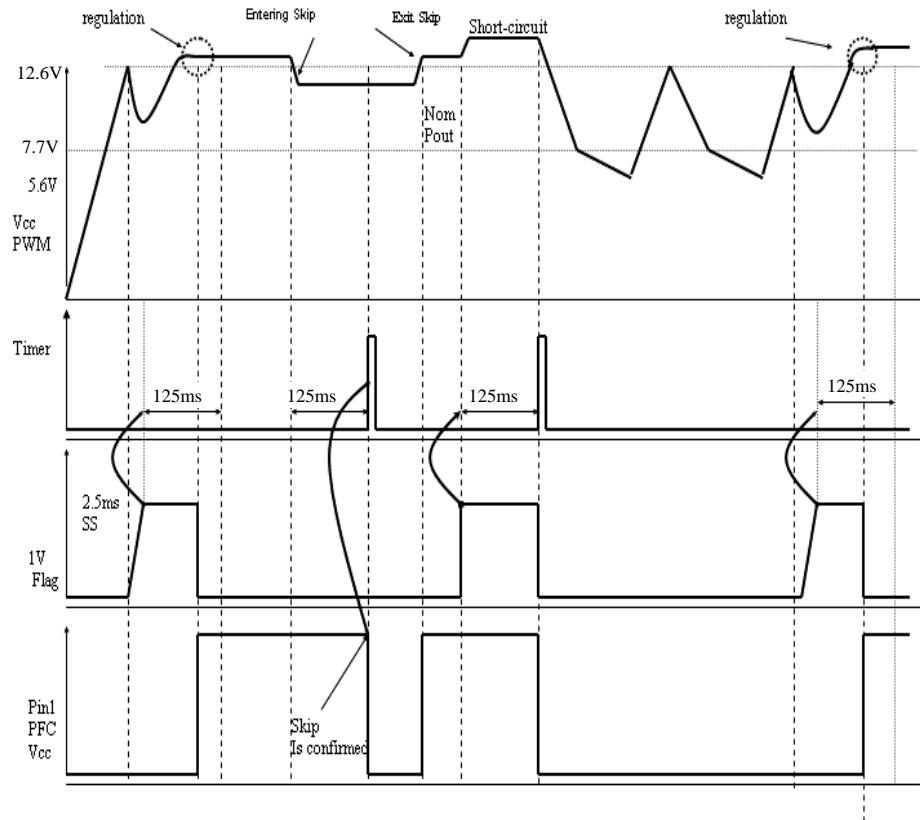

To resolve these issues the NCP1230 monitors the 1.0 V error flag. As soon as the internal 1.0 V error flag is asserted high, a 125 ms timer starts. If at the end of the 125 ms timeout period, the error flag is still asserted then the controller determines that there is a true fault condition and stops the PWM drive output, refer to Figure 35. When this occurs, Vcc starts to decrease because the power supply is locked out. When Vcc drops below UVLOlow (7.7 V typical), it enters a latch-off phase where the internal consumption is reduced down to 680  $\mu$ A (typical). The voltage on the Vcc capacitor continues to drop, but at a lower rate. When Vcc reaches the latch-off level (5.6 V), the current source is turned on and pulls Vcc above UVLOhigh. To limit the fault output power, a divide-by-two circuit is connected to the Vcc pin that requires two startup sequences before attempting to restart the power supply. If the fault has gone and the error flag is low, the controller resumes normal operations.

Under transient load conditions, if the error flag is asserted, the error flag will normally drop prior to the 125 ms timeout period and the controller continues to operate normally.

If the 125 msec timer expires while the NCP1230 is in the Skip Mode, SW1 opens and the PFC\_Vcc output will shut down and will not be activated until the fault goes away and the power supply resumes normal operations.

While in the Skip Mode, to avoid any thermal runaway it is desirable for the Burst duty cycle to be kept below 20% (the burst duty-cycle is defined as  $T_{pulse} / T_{fault}$ ).

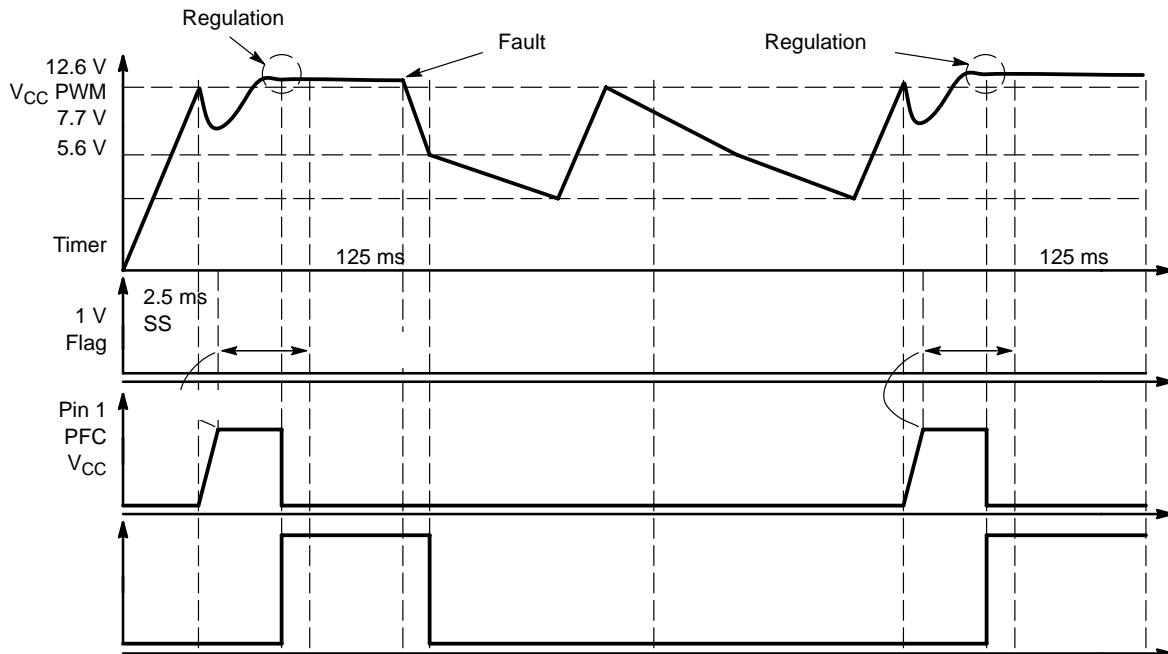

# NCP1230

**Figure 35.**

The latch-off phase can also be initiated, more classically, when  $V_{CC}$  drops below UVLO (7.7 V typical). During this fault detection method, the controller will not wait for the

125 ms time-out, or the error flag before it goes into the latch-off phase, operating in the skip mode under these conditions, refer to Figure 36.

**Figure 36.**

### Current Sense Input Pin Latch–Off

The NCP1230 features a fast comparator (Figure 34) that monitors the current sense pin during the controller off time. If for any reason the voltage on pin 3 increases above 3.0 V, the NCP1230 immediately stops the PWM drive pulses and permanently stays latched off until the bias supply to the NCP1230 is cycled down ( $V_{cc}$  must drop below 4.0 V, e.g. when the user unplugs the converter from the mains). This offers the designer the flexibility to implement an externally shutdown circuit (for example for overvoltage or overtemperature conditions). When the controller is latched off through pin 3 (current sense), SW1 opens and shuts off PFC\_  $V_{cc}$  output.

Figure 37 shows how to implement the external latch via a Zener diode and a simple PNP transistor. The PNP actually samples the Zener voltage during the OFF time only, hence leaving the CS information un–altered during the ON time. Various component arrangements can be made, e.g. adding a NTC device for the Over Temperature Protection (OTP).

Figure 37.

Connecting the PNP to the drive only activates the offset generation during Toff. Here is a solution monitoring the auxiliary  $V_{cc}$  rail.

### Drive Output

The NCP1230 provides a Drive Output which can be connected through a current limiting resistor to the gate of a MOSFET. The Driver output is capable of delivering drive pulses with a rise time of 40 ns, and a fall time of 15 ns through its internal source and sink resistance of 12.3 ohms (typical), measured with a 1.0 nF capacitive load.

### Startup Sequence

The NCP1230 has an internal High Voltage Startup Circuit (Pin 8) which is connected to the high voltage DC bus (Refer to Figure 36). When power is applied to the bus, the NCP1230 internal current source (typically 3.2 mA) is biased and charges up the external  $V_{cc}$  capacitor on pin 6, refer to Figure 38. When the voltage on pin 6 ( $V_{cc}$ ) reaches

$V_{ccoff}$  (12.6 V typically), the current source is turned off reducing the amount of power being dissipated in the chip. The NCP1230 then turns on the drive output to the external MOSFET in an attempt to increase the output voltage and charge up the  $V_{cc}$  capacitor through the Vaux winding in the transformer.

During the startup sequence, the controller pushes for the maximum peak current, which is reached after the 2.5 ms soft–start period. As soon as the maximum peak set point is reached, the internal 1.0 V Zener diode actively limits the current amplitude to 1.0 V/ $R_{sense}$  and asserts an error flag indicating that a maximum current condition is being observed. In this mode, the controller must determine if it is a normal startup period (or transient load) or is the controller is facing a fault condition. To determine the difference between a normal startup sequence, and a fault condition, the error flag is asserted, and the 125 ms timer starts to count down. If the error flag drops prior to the 125 ms time–out period, the controller resets the timer and determines that it was a normal startup sequence and enables the low impedance switch (SW1), enabling the PFC\_  $V_{cc}$  output.

If at the end of the 125 ms period the error flag is still asserted, then the controller assumes that it is a fault condition and the PWM controller enters the skip mode and does not enable the PFC\_  $V_{cc}$  output.

Figure 38.

ON Semiconductor recommends that the  $V_{cc}$  capacitor be at least 47  $\mu$ F to be sure that the  $V_{cc}$  supply voltage does not drop below  $V_{ccmin}$  (7.7 V typical) during standby power mode and unusual fault conditions.

### Soft–Start

The NCP1230 features an internal 2.5 ms soft–start circuit. As soon as  $V_{cc}$  reaches a nominal 12.6 V, the soft–start circuit is activated. The soft–start circuit output controls a reference on the minus (–) input to an amplifier (refer to Figure 39), the positive (+) input to the amplifier is the feedback input (divided by 3). The output of the amplifier drives a FET which clamps the feedback signal. As the soft–start circuit output ramps up, it allow the feedback pin input to the PWM comparator to gradually increased from near zero up to the maximum clamping level of 1.0 V/ $R_{sense}$ . This occurs over the entire 2.5 ms soft–start period until the supply enters regulation. The soft–start is also activated every time a restart is attempted. Figure 40 shows a typical soft–start up sequence.

Figure 40. Soft-Start is Activated during a Startup Sequence or an OCP Condition

## Frequency Jittering

Frequency jittering is a method used to soften the EMI signature by spreading out the average switching energy around the controller operating switching frequency. The

NCP1230 offers a nominal  $\pm 6.4\%$  deviation of the nominal switching frequency. The sweep sawtooth is internally generated and modulates the clock up and down with a 5 ms period. Figure 41 illustrates the NCP1230 behavior:

**Figure 41. An Internal Ramp is used to Introduce Frequency Jittering on the Oscillator Saw Tooth**

## Thermal Protection

An internal Thermal Shutdown is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated (165°C typically) the controller turns off the PWM Drive Output. When this occurs, Vcc will drop (the rate is dependent on the NCP1230 loading and the size of the Vcc capacitor) because the controller is no longer delivering drive pulses to the auxiliary winding charging up the Vcc capacitor. When Vcc

drops below 4.0 volts and the Vccreset circuit is activated, the controller will restart. If the user is using a fixed bias supply (the bias supply is provided from a source other than from an auxiliary winding, refer to the typical application ) and Vcc is not allow to drop below 4.0 volts under a thermal shutdown condition, the NCP1230 will not restart. This feature is provided to prevent catastrophic failure from accidentally overheating the device.

## PACKAGE DIMENSIONS

SOIC-7  
D1 SUFFIX  
CASE 751U-01  
ISSUE C

### NOTES:

1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
2. CONTROLLING DIMENSION: MILLIMETER.
3. DIMENSION A AND B ARE DATUMS AND T IS A DATUM SURFACE.
4. DIMENSION A AND B DO NOT INCLUDE MOLD PROTRUSION.
5. MAXIMUM MOLD PROTRUSION 0.15 (0.006) PER SIDE.

DIM	MILLIMETERS		INCHES	
	MIN	MAX	MIN	MAX
A	4.80	5.00	0.189	0.197
